December 27, 2017

Abstract

We consider planar networks of three curves that meet at two junctions with prescribed equal angles, minimizing a combination of the elastic energy and the length functional. We prove existence and regularity of minimizers, and we show some properties of the minimal configurations.

1 Introduction

In this paper we are interested in the minimization of the elastic energy among planar networks composed by three curves which we call 3-networks. In this still large class we consider the more special family of, what we call, Theta-networks. These are 3-networks whose curves are of class H^2 , regular and form 120 degrees at the two junctions.

We consider an energy given by the sum of the penalized elastic energies of each curve composing the network. Parametrizing each curve by γ^i , denoting with s^i is the arclength parameter and with k^i the (scalar) curvature, we set

$$F_\alpha(\Gamma) := \sum_{i=1}^3 \int_{\gamma^i} ((k^i)^2 + \alpha) ds^i, \quad \alpha > 0. \quad (1.1)$$

Although we are interested in this energy mainly from a theoretical point of view, we remind that it appears also in many mechanical and physical models (c.f. [13]) and in imaging sciences, see for instance [12].

Before embarking on the description of our work, let us briefly review the known results in the case of single closed curves. We remark that if we take $\alpha = 0$ in (1.1) the infimum of the elastic energy among closed curves is zero, but it is not a minimum. Indeed consider a sequence of circles \mathcal{C}_R with radius R , then the energy vanishes as $R \rightarrow \infty$, but the value zero is never attained. Adding a length penalization to the functional is needed to have a well-posed problem. Due to the behaviour under rescaling of the elastic energy and of the length it is easy to see that, up to rescaling, one can reduce to consider the functional F_1 (see [3] and Section 2). The minimum of the energy F_1 is 4π and the unique minimizer is the circle of radius 1.

Stationary curves for the functional F_1 (or more generally F_α) are usually called *elasticae*. In [11] Langer and Singer provide a complete classification of elasticae. In particular, the authors prove that the circle and the “Figure Eight” (or a multiple cover of one of these two) are the unique closed planar elasticae [11, Theorem 0.1 (a)]. Let us observe that minimizing the elastic energy on closed curves with a fixed length constrained is, up to rescaling, equivalent to minimizing the penalized elastic energy on the same class of curves, see [3] for the details. Moreover we notice that penalizing the length is not the unique way to obtain a well-posed and non-trivial minimization problem, for instance one can penalize the area enclosed by the curves [2, 8] (in this case the curves are necessary embedded) or confine the curves in a bounded domain of \mathbb{R}^2 [4, 7].

Figure 1: Left: A Theta-network. Right: The “Figure Eight”, that is, the unique closed planar elastica with self-intersections.

Let us now come back to the networks’ case. Similarly to what happens with curves, if we state the minimization problem among regular 3-networks of class H^2 again the infimum is zero and never attained. To avoid such inconvenience we restrict to the class of Theta-networks: we ask that the unit tangent vectors to the three curves at the junctions form angles of 120 degrees. In fact to find a lower bound on the energy it would be enough to require that the angles are fixed and different from zero (see also [3] for a long digression about the possible choices to get a well-posed problem). Notice however that also in this class the problem has some form of degeneracy. Indeed consider a minimizing sequence of Theta-networks Γ_n , then as $n \rightarrow \infty$ the length of some curves could go to zero. More precisely we are able to prove that the length of at most one curve can go to zero. The (H^2 -weak) limit is either a Theta-network, or it is composed by two drops (Definition 4.2) forming angles in pair of 120 and 60 degrees. A key point of the proof are careful estimates on the energy, based on a generalization of the classical Gauss-Bonnet theorem (Theorem A.1).

Being the class of Theta-networks not closed, we enlarge the class of networks into one where we gain compactness. We introduce the extension \bar{F} of the original functional F (Definition 3.2) defined for all 3-networks and we prove existence of minimizers for \bar{F} (Corollary 3.6).

This is clearly not enough to show existence of minimizers for F among Theta-network. To conclude the argument we prove that \bar{F} is the relaxation (w.r.t. the weak H^2 topology) of F and then we show that the minimizers of \bar{F} actually belong to the initial class of Theta-networks.

The proof of the latter claim is quite tricky, and is one of the main results of this paper. We briefly describe the structure of the argument. We first establish the existence of a minimizer for the penalized elastic energy in the class of drops, and compute its energy. The unique minimizer (up to isometries of \mathbb{R}^2) turns out to be one of the two drops of the “Figure Eight”. Following the

approach introduced in [5], in [3] we show that the energy of the minimal drop is approximately 10.60375 (see Lemma 4.9). Then we suppose by contradiction that a minimizer of \bar{F} is composed by two drops. Its energy is greater or equal than the one of the “Figure Eight”. It is therefore enough to exhibit a Theta-network with strictly less energy to get the contradiction. The energy of the standard double bubble (easy to compute) is strictly less than the energy of the “Figure Eight” and this allows us to conclude the proof.

The plan of the paper is the following: In Section 2 we introduce the penalized elastic energy functional for Theta-networks and we state some basic properties of this energy. Section 3 is devoted to prove existence of minimizers for the relaxed functional. In Section 4 we consider the minimization problem of the energy in the class of drops. We describe the unique minimizer (up to isometries of \mathbb{R}^2), whose energy is computed in [3]. Using this characterization we are able to prove that the minimizers of our problem for networks are in the original smaller class of Theta-networks, and that each curve of a minimizer is injective (see Proposition 4.11). We also shortly discuss the minimization problem for networks with two triple junctions and prescribed non-equal angles. We conclude the paper with an estimate, contained in Appendix A, on the total variation of the curvature for continuous, piecewise $W^{2,1}$, closed curves with self-intersections. This result can be seen as a variant of the classical Gauss–Bonnet Theorem for curves.

2 Notation and preliminary definitions

In this section we introduce the penalized elastic energy and the notion of Theta-network. We also list some useful properties, whose proofs are based on routine computations (we refer to [3] for the details).

When we consider a curve γ , we mean a parametrization $\gamma : [0, 1] \rightarrow \mathbb{R}^2$. A curve is of class C^k (or H^k) with $k = 1, 2, \dots$ if it admits a parametrization γ of class C^k (or H^k , respectively). A curve at least of class C^1 is said to be regular if $|\partial_x \gamma(x)| \neq 0$ for every $x \in [0, 1]$.

For regular curves we denote by s the arclength parameter and use that $\partial_s = \frac{\partial_x}{|\partial_x \gamma|}$.

- If a curve γ is at least of class C^1 and regular we are allowed to speak of its unit tangent vector $\tau = \partial_s \gamma = \frac{\partial_x \gamma}{|\partial_x \gamma|}$.
- The unit normal vector ν to γ is defined as the anticlockwise rotation of $\frac{\pi}{2}$ of τ .
- If a curve γ is at least of class C^2 and regular we define its scalar curvature as the scalar function k such that $\partial_s^2 \gamma = k\nu$.

Notice that we will adopt the following convention for integrals,

$$\int_{\gamma} f(\gamma, \tau, \nu, \dots) ds = \int_0^1 f(\gamma, \tau, \nu, \dots) |\partial_x \gamma| dx,$$

as the arclength measure is given by $ds = |\partial_x \gamma| dx$ on every curve γ .

3-networks and Theta-networks

Definition 2.1. A 3-network is a connected set in the plane, union of three curves that meet at two triple junctions. A 3-network is said to be *regular* if every curve admits a parametrization γ^i which is regular, *injective* if every curve is injective and *of class H^2* if every curve is of class H^2 .

A *Theta-network* is a 3-network such that the three curves are of class H^2 , and meet at the triple junctions with angles of 120 degrees.

Notice that the curves of a Theta-network can intersect each other or have self-intersections. Calling P^1, P^2 the two triple junctions, without loss of generality we can parametrized the three curves in such a way that $P^1 = \gamma^1(0) = \gamma^2(0) = \gamma^3(0)$ and $P^2 = \gamma^1(1) = \gamma^2(1) = \gamma^3(1)$. It is also not restrictive to require that P^1 coincides with the origin, and to fix the unit tangent vectors to the curves at P^1 as $\tau^1(0) = (1/2, \sqrt{3}/2)$, $\tau^2(0) = (-1, 0)$ and $\tau^3(0) = (1/2, -\sqrt{3}/2)$. The only information we have at P^2 is that $\tau^1(1) + \tau^2(1) + \tau^3(1) = 0$.

Figure 2: Two examples of Theta-networks.

Penalized elastic energy

Given a Theta-network Γ we let $L(\Gamma) := \sum_{i=1}^3 \int_{\gamma^i} 1 ds^i$ be its total length, $L(\gamma^i)$ be the length of the i -th curve of the network, and $E(\Gamma) := \sum_{i=1}^N \int_{\gamma^i} (k^i)^2 ds^i$ be its total elastic energy. Then we consider the penalized elastic energy, defined as:

$$F_\alpha(\Gamma) := E(\Gamma) + \alpha L(\Gamma), \quad \alpha > 0. \quad (2.1)$$

We are interested in the following minimization problem:

Problem 2.2. Is

$$\inf\{F_1(\Gamma) \mid \Gamma \text{ is a Theta-network}\} \text{ attained?}$$

Reduction to the case $\alpha = 1$

It is not restrictive to consider only F_1 in Problem 2.2. Indeed, for any Theta-network Γ , using the scaling properties of the length and of the elastic energy we have

$$F_1(\Gamma) = \alpha^{-\frac{1}{2}} F_\alpha\left(\alpha^{-\frac{1}{2}}\Gamma\right) \text{ for any } \alpha > 0. \quad (2.2)$$

As a consequence if Γ_1 is a stationary point for F_1 , then the rescaled network $\Gamma_\alpha := \alpha^{-\frac{1}{2}}\Gamma_1$ is a stationary point for F_α , and viceversa.

Hence, from now on we can fix $\alpha = 1$ and consider the energy

$$F(\Gamma) := F_1(\Gamma).$$

In the following, with a little abuse of notation, we consider the same functional not only on Theta-networks but also on continuous piecewise H^2 curves. In all cases F is given by the sums of the elastic energy and of the length for each H^2 -piece of curve.

Optimal rescaling and equipartition of the energy for the minimizers

Consider a Theta-network Γ and the rescaled network $\tilde{R}\Gamma$ of Γ with the factor $\tilde{R} := \sqrt{\frac{E(\Gamma)}{L(\Gamma)}}$ with $E(\Gamma)$ and $L(\Gamma)$ as defined above (2.1). Then for every rescaling of factor $R > 0$ of Γ it holds

$$F(\tilde{R}\Gamma) \leq F(R\Gamma),$$

that is, the network $\tilde{R}\Gamma$ is the optimal rescaling (for the energy F) of the network Γ .

We notice that for each optimal rescaled network, and in particular for the minimizers of F (if there exist), there is an equipartition of the energy. Indeed, called \tilde{R} the optimal rescaling of a Theta-network Γ , then

$$E(\tilde{R}\Gamma) = \sqrt{E(\Gamma)L(\Gamma)} = L(\tilde{R}\Gamma), \quad (2.3)$$

so that

$$F(\tilde{R}\Gamma) = 2E(\tilde{R}\Gamma) = 2\sqrt{E(\Gamma)L(\Gamma)}.$$

Remark 2.3. Also in the case of networks, using scaling arguments one can see that minimizing the elastic energy with a penalization of the length is equivalent, up to rescaling, to the minimization problem with a fixed length constraint on the entire network. For more details see [3, Sec.5].

Reparametrization with constant velocity

From now on we require that the regular curves of a Theta-network are parametrized on $[0, 1]$ with constant speed equal to the length. In this case the functional (2.1) can be written as

$$F(\Gamma) = \sum_{i=1}^3 \frac{1}{L^3(\gamma^i)} \int_0^1 (\gamma_{xx}^i)^2 dx + L(\gamma^i). \quad (2.4)$$

Upper bound on the energy

The standard double bubble $\mathcal{B}_{\bar{r}}$ composed by a segment and two circular arcs of radius $\bar{r} = \sqrt{\frac{8\pi}{3\sqrt{3}+8\pi}}$ is the optimal rescaling of the standard double bubble and hence the one of less energy between all possible standard double bubble. Its energy is given by

$$E(\mathcal{B}_{\bar{r}}) = \frac{2}{3} \sqrt{8\pi(8\pi + 3\sqrt{3})} \approx 18.4059. \quad (2.5)$$

Then clearly

$$\inf\{F(\Gamma) \mid \Gamma \text{ is a Theta-network}\} \leq \frac{2}{3} \sqrt{8\pi(8\pi + 3\sqrt{3})} < +\infty. \quad (2.6)$$

Figure 3: Standard double bubble

Lower bound on the energy

Lemma 2.4. *Let $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ be a regular, continuous, piecewise H^2 curve and suppose that there exists a strictly positive constant c such that $\int_{\gamma} |k| ds \geq c$, then $F(\gamma) \geq 2c$.*

Proof. Using Hölder inequality we get

$$c \leq \int_{\gamma} |k| ds \leq \left(\int_{\gamma} k^2 ds \right)^{\frac{1}{2}} (L(\gamma))^{\frac{1}{2}} = (E(\gamma)L(\gamma))^{\frac{1}{2}},$$

then

$$F(\gamma) = E(\gamma) + L(\gamma) \geq \frac{c^2}{L(\gamma)} + L(\gamma) \geq 2c. \quad (2.7)$$

□

Lemma 2.5. *Let Γ be a Theta-network. Then $F(\Gamma) \geq 4\pi \approx 12.5663\dots$*

Proof. Let $\Gamma = \{\gamma^1, \gamma^2, \gamma^3\}$ be a Theta-network and consider the piecewise H^2 closed curves $\Gamma_{i,j} = \{\gamma^i, \gamma^j\}$ with $i \neq j \in \{1, 2, 3\}$. By Corollary A.3, we get that $\int_{\Gamma_{i,j}} |k| ds \geq \frac{4\pi}{3}$. and by the previous Lemma $F(\Gamma_{i,j}) \geq \frac{8\pi}{3}$. Then

$$F(\Gamma) = \frac{1}{2} (F(\Gamma_{1,2}) + F(\Gamma_{2,3}) + F(\Gamma_{3,1})) \geq 4\pi. \quad (2.8)$$

□

3 Existence of minimizers

As explained in the Introduction we introduce now the functional \bar{F} , an extension of F to all 3-networks of class H^2 . We prove existence of a minimizer for \bar{F} in this larger space and show that \bar{F} is the relaxation of F with respect to H^2 weak convergence.

Definition 3.1. A “degenerate” Theta-network is a network composed by two regular curves γ^1, γ^2 of class H^2 , forming angles in pairs of 120 and 60 degrees and by a curve γ^3 of length zero.

Figure 4: Three examples of “degenerate” Theta–network.

From now on we parametrized all the regular curves of a 3–network on $[0, 1]$ and with constant speed equal to their length. In particular, the energy F on regular 3–networks is given as in (2.4).

Definition 3.2. We define the functional \bar{F} on 3–networks Γ of class H^2 as follows

$$\bar{F}(\Gamma) = \begin{cases} \sum_{i=1}^3 \frac{1}{L^3(\gamma^i)} \int_0^1 (\gamma_{xx}^i)^2 dx + L(\gamma^i) & \text{if } \Gamma \text{ is Theta–network,} \\ \sum_{i=1}^2 \frac{1}{L^3(\gamma^i)} \int_0^1 (\gamma_{xx}^i)^2 dx + L(\gamma^i) & \text{if } \Gamma \text{ is a “degenerate” Theta network,} \\ +\infty & \text{otherwise} \end{cases}$$

By definition the two functionals F and \bar{F} coincide on Theta–networks. Notice that when we speak of the set of all 3–networks of class H^2 we do not ask that the lengths of the three curves constituting the network are positive. In particular, we do not require regularity of the curves.

Theorem 3.3. *The functional \bar{F} is the relaxation of the functional F in H^2 , that is for any 3–network Γ of class H^2*

$$\bar{F}(\Gamma) = \inf \left\{ \liminf_{n \rightarrow \infty} F(\Gamma_n) : \Gamma_n \rightharpoonup \Gamma \text{ weakly in } H^2, \text{ with } \Gamma_n \text{ Theta–network} \right\}.$$

Before proving Theorem 3.3 we discuss the compactness properties and the semicontinuity of the functional \bar{F} .

Compactness

As for the Theta–networks, without loss of generality we can ask that one of the two triple junctions of a 3–network coincides with the origin.

Proposition 3.4. *Let $\Gamma_n = \{\gamma_n^1, \gamma_n^2, \gamma_n^3\}$ be a sequence of 3–networks of class H^2 such that*

$$\limsup_n \bar{F}(\Gamma_n) < +\infty.$$

Then Γ_n converge, up to a subsequence, weakly in H^2 and strongly in $C^{1,\alpha}$ with $\alpha \in (0, \frac{1}{2})$ to Γ . The network Γ is either a Theta–network or a “degenerate” Theta–network.

Proof. Up to a subsequence (not relabeled) all Γ_n are either Theta–networks or “degenerate” Theta–networks.

1. Suppose they are all Theta-networks, i.e. $\Gamma_n = \{\gamma_n^1, \gamma_n^2, \gamma_n^3\}$. For $x \in \{0, 1\}$ we have $\gamma_n^1(x) = \gamma_n^2(x) = \gamma_n^3(x)$ and $\sum_{i=1}^3 \tau_n^i(x) = 0$.

From the bound on the energy it follows that the length of each curve of the network Γ_n is uniformly bounded from above. As a consequence, for $i = 1, 2, 3$

$$\int_0^1 (\gamma_{n,xx}^i)^2 dx \leq \int_0^1 \frac{(\gamma_{n,xx}^i)^2}{L(\gamma_n^i)^3} dx L(\gamma_n^i)^3 \leq \left(\sum_{i=1}^3 \int_0^1 \frac{(\gamma_{n,xx}^i)^2}{L(\gamma_n^i)^3} dx \right) L(\gamma_n^i)^3 \leq F(\Gamma_n) L(\gamma_n^i)^3,$$

from which one derives a uniform bound on the L^2 -norm of the second derivatives. As each network contains the origin and the curves are parametrized with constant speed (equal to the length) we have $\|\gamma_n^i\|_\infty \leq C$ and $\|\gamma_{n,x}^i\|_\infty \leq C'$ with C, C' positive constants. Then, up to a subsequence (not relabeled), $\gamma_n^i \rightharpoonup \gamma_\infty^i$ weakly in $H^2(0, 1)$ and $\gamma_n^i \rightarrow \gamma_\infty^i$ strongly in $C^{1,\alpha}([0, 1])$ for every $\alpha \in (0, \frac{1}{2})$. It remains to understand what the limit is.

We claim that for at least two of the curves we have uniform bounds from below on the length. Indeed, suppose by contradiction that the length of at least two curves of Γ_n tends to zero. Let us say that $L(\gamma_n^2) \rightarrow 0$ and $L(\gamma_n^3) \rightarrow 0$. Calling $\Gamma_{n,2,3} = \{\gamma_n^2, \gamma_n^3\}$, by Corollary A.3 we have

$$\bar{F}(\Gamma_n) \geq \int_{\Gamma_{n,2,3}} k^2 ds \geq \frac{16\pi^2}{9(L(\gamma_n^2) + L(\gamma_n^3))} \rightarrow +\infty \quad (3.1)$$

a contradiction. Hence on at least two of the sequences $\gamma_n^i, i \in \{1, 2, 3\}$, the length is uniformly bounded from below.

- Suppose that none of the lengths of the curves in Γ_n goes to zero. Then due to the strong convergence in C^1 of $\gamma_n^i \rightarrow \gamma_\infty^i$ for all $i \in \{1, 2, 3\}$, all the tangents τ_∞^i are well defined and also the conditions at the junctions $\sum_{i=1}^3 \tau_\infty^i(x) = 0$ and $\gamma_\infty^1(x) = \gamma_\infty^2(x) = \gamma_\infty^3(x)$, $x \in \{0, 1\}$, are fulfilled. Hence Γ is a Theta-network.
- Suppose now that the length of one curve of Γ_n tends to zero. Let us fix $L(\gamma_n^3) \rightarrow 0$. We have

$$\begin{aligned} |\tau_n^3(1) - \tau_n^3(0)| &= \frac{1}{L(\gamma_n^3)} \left| \int_0^1 \gamma_{n,xx}^3(x) dx \right| \\ &\leq \frac{1}{L(\gamma_n^3)} \left(\int_0^1 (\gamma_{n,xx}^3(x))^2 dx \right)^{1/2} \left(\int_0^1 1 dx \right)^{1/2} \\ &= \left(\int_0^1 \frac{(\gamma_{n,xx}^3(x))^2}{(L(\gamma_n^3))^3} dx \right)^{1/2} (L(\gamma_n^3))^{1/2} \\ &\leq (\bar{F}(\Gamma_n))^{1/2} (L(\gamma_n^3))^{1/2} \leq C(L(\gamma_n^3))^{1/2}. \end{aligned}$$

Hence $|\tau_n^3(1) - \tau_n^3(0)| \rightarrow 0$ as $n \rightarrow \infty$, that combined with the C^1 convergence gives that Γ is a “degenerate” Theta-network.

2. Suppose instead that all the terms of Γ_n are “degenerate” Theta-networks, i.e. $\Gamma_n = \{\gamma_n^1, \gamma_n^2\}$. In this case, none of the length goes to zero. Indeed, suppose by contradiction that $L(\gamma_n^i) \rightarrow 0$

as $n \rightarrow \infty$, for some $i \in \{1, 2\}$, using Corollary A.2 we know that

$$\pi \leq \left(\int_{\gamma_n^i} k^2 \, ds \right)^{\frac{1}{2}} L(\gamma_n^i)^{\frac{1}{2}},$$

and hence

$$\bar{F}(\Gamma_n) \geq \int_{\gamma_n^i} k^2 \, ds > \frac{\pi^2}{L(\gamma_n^i)} \rightarrow +\infty,$$

a contradiction. Due to the upper bound on the length, repeating the same arguments as before we have again that γ_n^i converges weakly in H^2 and strongly in C^1 to γ_∞^i , for $i = 1, 2$. As no length goes to zero and there is convergence in C^1 , the angles between the curves are preserved passing to the limit. As a consequence, $\Gamma = \{\gamma_\infty^1, \gamma_\infty^2\}$ is a “degenerate” Theta-network.

□

Semicontinuity

Proposition 3.5. *The functional \bar{F} on 3-networks of class H^2 is weakly lower semicontinuous in H^2 .*

Proof. Let Γ_n be a sequence of 3-networks converging weakly in H^2 to Γ_∞ . Passing to a subsequence (not relabeled) we can reduce to prove that $\lim_n \bar{F}(\Gamma_n) \geq \bar{F}(\Gamma_\infty)$. If $\lim_n \bar{F}(\Gamma_n) = \infty$ there is nothing to prove, and hence we can suppose that the limit of $\bar{F}(\Gamma_n)$ is finite. As a consequence, we can assume that all the terms of Γ_n are either Theta-networks or “degenerate” Theta-networks.

For a single regular H^2 curve γ (of positive length) the functional $\frac{1}{L^3(\gamma)} \int_0^1 \gamma_{xx}^2 \, dx + L(\gamma)$ is well defined and also weakly lower semicontinuous on this class. This follows from the continuity of the length and the lower semicontinuity of the L^2 norm. In the case in which Γ_n and the limit Γ are all Theta-networks (or all “degenerate” Theta-networks), the claim follows using for all the three curves (or the two curves) of the network the previous argument for a single curve. It remains to consider the case in which Γ_n are Theta-networks and Γ is a “degenerate” Theta-network. We may assume that $L(\gamma^3) = 0$ and the claim follows also in this case with the same arguments noticing that

$$\sum_{i=1}^3 \frac{1}{L^3(\gamma_n^i)} \int_0^1 ((\gamma_{xx})_n^i)^2 \, dx + L(\gamma_n^i) \geq \sum_{i=1}^2 \frac{1}{L^3(\gamma_n^i)} \int_0^1 ((\gamma_{xx})_n^i)^2 \, dx + L(\gamma_n^i).$$

and then we can reduce to the case of “degenerate” Theta-networks.

□

Existence

Combining the compactness and the lower semicontinuity results we obtain the following:

Corollary 3.6 (Existence of minimizer for \bar{F}). *There exists Γ_{\min} Theta-network or “degenerate” Theta-network minimizer of the functional \bar{F} among 3-networks of class H^2 .*

We can finally prove that the functional \bar{F} is the relaxation of F on Theta-networks in H^2 .

Proof of Theorem 3.3. The claim follows once we have proved that for every “degenerate” Theta-network Γ there exists a sequence Γ_n of Theta-networks such that

$$\Gamma_n \rightharpoonup \Gamma \text{ in } H^2 \text{ and } F(\Gamma_n) \rightarrow \overline{F}(\Gamma).$$

Let us denote by γ_1, γ_2 the two curves constituting the “degenerate” Theta-network Γ . Without loss of generality we put the four-point $P := \gamma^1(0) = \gamma^1(1) = \gamma^2(0) = \gamma^2(1)$ at the origin and orient the network in such a way that $\tau^1(0)$ forms an angle of 60 degrees with the x -axis (in particular the second component of the vector is positive). As the angles at P are fixed, $\tau^1(1)$ forms an angle of -60 degrees with the x -axis (in particular the second component of the vector is negative). Then by the intermediate value Theorem there exists at least one point $t_1 \in [0, 1]$ such that $\tau^1(t_1)$ is horizontal (the second component of the vector is zero). Repeating the same argument for the curve γ^2 one finds also a $t_2 \in [0, 1]$ such that $\tau^2(t_2)$ is horizontal. Call $Q^1 = \gamma^1(t_1)$ and $Q^2 = \gamma^2(t_2)$.

Figure 5: Construction of the recovery sequence.

We construct the (recovery) sequence of Theta-networks Γ_n cutting Γ at the points P, Q^1 and Q^2 and gluing three horizontal segments of length $1/n$ (see Figure 5). Then Γ_n is indeed a Theta-network for each n and it is easy to see that $\Gamma_n \rightharpoonup \Gamma$ weakly in H^2 . Moreover $F(\Gamma_n) \rightarrow \overline{F}(\Gamma)$ as the pieces of $F(\Gamma_n)$ and $\overline{F}(\Gamma)$ with non zero curvature are the same and the total length of Γ_n converge to the length of Γ as $n \rightarrow \infty$. \square

4 Properties of minimizers

In this section we want to prove some properties of the minimizers for the relaxed functional \overline{F} . In particular we show that the minimizers are actually Theta-networks and hence we give a positive answer to Problem 2.2. We get our result showing that the minimal energy of a “degenerate” Theta-network is higher than the energy of a given competitor among Theta-networks (the standard double bubble). A tool to obtain the desired lower bound is studying the minimization problem for drops and double drops.

Before studying these other minimization problems we shortly discuss the Euler-Lagrange equations and the regularity of the curves constituting a \overline{F} -minimizing network.

Proposition 4.1. *Let $\tilde{\Gamma}$ be a minimizer for \overline{F} and $\tilde{\gamma}$ be any of the regular curves constituting $\tilde{\Gamma}$. Then*

1. the curve $\tilde{\gamma}$ minimizes the penalized elastic energy $\int_{\gamma} k^2 + 1 ds$ among regular H^2 curves $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ satisfying the same boundary conditions as $\tilde{\gamma}$, i.e. $\gamma(x) = \tilde{\gamma}(x)$ and $\partial_s \gamma(x) = \partial_s \tilde{\gamma}(x)$ at $x \in \{0, 1\}$.
2. the curve $\tilde{\gamma}$ is $C^\infty([0, 1])$ and solves the equation

$$2\partial_s^2 k + k^3 - k = 0 \text{ on } (0, 1). \quad (4.1)$$

Proof. 1. Let Γ be the regular network that we obtain from the network $\tilde{\Gamma}$ replacing the curve $\tilde{\gamma}$ with a regular H^2 curve γ that satisfies the same boundary conditions as $\tilde{\gamma}$, as explained in the statement. Then Γ is a Theta-network if $\tilde{\Gamma}$ is a Theta-network, whereas Γ is a “degenerate” Theta-network if so is $\tilde{\Gamma}$. Since by assumption $\overline{F}(\tilde{\Gamma}) \leq \overline{F}(\Gamma)$ and we did not change the other curves (or the other curve) constituting the network, it follows that $\tilde{\gamma}$ minimizes the penalized elastic energy among curves satisfying the same boundary conditions.

2. For smooth curves the Euler-Lagrange equation (4.1) is computed in [10]. In this weak setting, as usual one starts from the first variation that corresponds to the weak formulation of (4.1). Then by appropriate choice of the test functions in $H_0^2(0, 1)$ one show first that $k \in L^\infty$, then $k \in W^{1, \infty}$ and finally that $\tilde{\gamma} \in H^4$. By elliptic regularity and a bootstrap argument one gets that $\tilde{\gamma}$ is in $C^\infty([0, 1])$ and in particular that (4.1) is satisfied pointwise. These reasonings have been carried out in details for instance in [3, Prop.4.1]. □

4.1 Drops

Definition 4.2. We call *drop* a regular curve $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ of class H^2 such that $\gamma(0) = \gamma(1)$.

Notice that in the definition of drops we do not impose any assumption on the tangents at $x = 0$ and at $x = 1$. In the following every time we consider a drop, without loss of generality, the point $\gamma(0) = \gamma(1)$ is fixed at the origin of the axis.

Figure 6: An example of a drop.

We consider now the restriction of our minimization problem to the class of drops. Let us recall that F denotes also the penalized elastic energy functional on regular H^2 curves $\gamma : [0, 1] \rightarrow \mathbb{R}^2$, that is $F(\gamma) = \int_{\gamma} k^2 + 1 ds$.

Problem 4.3. Is

$$\inf\{F(\gamma) \mid \gamma \text{ is a drop}\} \text{ attained?}$$

We observe that Problem 4.3 is slightly different from Problem 2.2, since no condition is imposed on the angle at $\gamma(0) = \gamma(1)$. Since the circle of radius 1 is a particular drop, we immediately get

$$m := \inf\{F(\gamma) \mid \gamma \text{ is a drop}\} \leq 4\pi < \infty. \quad (4.2)$$

Theorem 4.4 (Existence of minimizers). *There exists a drop $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ such that $F(\gamma) = m$. That is, a minimizer for Problem 4.3 exists.*

Proof. We consider a minimizing sequence of drops $\gamma_n : [0, 1] \rightarrow \mathbb{R}^2$. Since $L(\gamma) \leq F(\gamma)$, the length of the curves $L(\gamma_n)$ is uniformly bounded from above. Moreover combining Corollary A.2 and Hölder inequality we obtain

$$\pi \leq \int_{\gamma_n} |k_n| ds_n \leq \left(\int_{\gamma_n} k_n^2 ds_n \right)^{1/2} (L(\gamma_n))^{1/2} \leq (F(\gamma_n))^{1/2} (L(\gamma_n))^{1/2}.$$

As $F(\gamma_n) \leq C < \infty$, for all $n \in \mathbb{N}$ we get the uniform bound

$$0 < \frac{\pi^2}{C} \leq L(\gamma_n) \leq C. \quad (4.3)$$

By parametrizing the sequence with constant velocity equal to the length we obtain $\|\gamma_{n,x}\|_\infty = L(\gamma_n) \leq C$. As we have fixed the point $\gamma_n(0) = \gamma_n(1)$ at the origin, we also get $\|\gamma_n\|_\infty \leq C$. By (2.4) we obtain $\frac{1}{L^3(\gamma_n)} \int_0^1 \gamma_{n,xx}^2 dx \leq F(\gamma_n) \leq C$, thus we have

$$\|\gamma_{n,xx}\|_2 \leq L^3(\gamma_n)C \leq C^4.$$

Then there exist a subsequence γ_{n_k} and $\gamma \in H^2$ such that γ_{n_k} converge weakly in H^2 and strongly in $C^{1,\alpha}$ (with $\alpha \in (0, \frac{1}{2})$) to γ . Because of (4.3) the limit has strictly positive length. The functional F is weakly lower semicontinuous, hence $F(\gamma) \leq \lim_k F(\gamma_{n_k}) = m$, and this concludes the proof. \square

In Subsection 4.3 we give explicitly the unique (up to isometries of \mathbb{R}^2) minimizer for Problem 4.3.

4.2 Double drops

Definition 4.5. We call

1. *double drop* a 2-network $\mathcal{D} = \{\gamma^1, \gamma^2\}$, such that for $i \in \{1, 2\}$ the curves $\gamma^i : [0, 1] \rightarrow \mathbb{R}^2$ are drops and there exists a four-point $\gamma^1(0) = \gamma^1(1) = \gamma^2(0) = \gamma^2(1) =: P$;
2. *symmetric double drop* \mathcal{SD} a double drop in which the two drops are symmetric with respect to the four-point P .

Notice that a symmetric double drop can be seen as a double drop $\mathcal{D} = \{\gamma_1, \gamma_2\}$ where $\gamma_2(t) = -\gamma_1(1-t)$ for all $t \in [0, 1]$. The penalized elastic energy for a network of two curves is simply the sum of the penalized elastic energy of the curves and for a symmetric double drop $\mathcal{SD} = \{\gamma^1, \gamma^2\}$ we have that $F(\mathcal{SD}) = 2F(\gamma^1) = 2F(\gamma^2)$.

Again, as for the drops, for simplicity we fix the four-point P at the origin of the axes. From the definition of symmetric double drop we have that the curves γ^1 and γ^2 form at P angles equal in pairs.

Remark 4.6. Due to symmetry any symmetric double drop is globally of class H^2 . More precisely: given a symmetric double drop $\mathcal{SD} : [0, 1] \rightarrow \mathbb{R}^2$, there exists a reparametrization of \mathcal{SD} such that \mathcal{SD} is a closed curve globally of class H^2 .

4.3 Characterization of optimal drops

Lemma 4.7. *Let us call*

$$\begin{aligned} n &:= \inf\{F(\mathcal{D}) \mid \mathcal{D} \text{ is a double drop}\} \\ \tilde{n} &:= \inf\{F(\mathcal{SD}) \mid \mathcal{SD} \text{ is a symmetric double drop}\} \\ \bar{n} &:= \inf\{F(\varphi) \mid \varphi : \mathbb{S}^1 \rightarrow \mathbb{R}^2, \varphi \text{ is a regular curve of class } H^2 \\ &\quad \text{and there exists at least two points } s_1 \neq s_2 \in \mathbb{S}^1 \text{ such that } \gamma(s_1) = \gamma(s_2)\}. \end{aligned}$$

Then

$$n = \tilde{n} = \bar{n} = 2m$$

with m as defined in (4.2). Moreover all the infima are minima.

Proof. By Definition 4.5 and Remark 4.6 one sees that $n \leq \bar{n} \leq \tilde{n}$. Moreover in these three minimization problems a candidate for the minimum is the symmetric double drop $\mathcal{D}_{\min} = \{\gamma^1, \gamma^2\}$ with γ^1 a minimizer for Problem 4.3 (whose existence is established in Theorem 4.4) and γ^2 the curve such that $\gamma^2(t) = -\gamma^1(1-t)$, $t \in [0, 1]$. Since $F(\mathcal{D}_{\min}) = 2m$, with m defined in (4.2), it follows that

$$n \leq \bar{n} \leq \tilde{n} \leq 2m.$$

On the other hand, a double drop \mathcal{D} is a union of two different drops $\varphi^i : [0, 1] \rightarrow \mathbb{R}^2$ of class H^2 . We can suppose without loss of generality that $F(\varphi^2) \geq F(\varphi^1)$, hence

$$F(\mathcal{D}) = F(\varphi^1) + F(\varphi^2) \geq 2F(\varphi^1) \geq 2m.$$

We conclude that $2m = \tilde{n} \geq \bar{n} \geq n \geq 2m$ and, that in particular, the three infima are actually equal. Since $F(\mathcal{D}_{\min}) = 2m$ and \mathcal{D}_{\min} belongs to all three sets, it is a minimizer for all three problems. \square

We are now ready to characterize the optimal drop of Theorem 4.4. Let us recall that Langer and Singer established in [11, Theorem 0.1(a)] that the ‘‘Figure Eight’’ is the unique closed planar elastica (up to multiple coverings and isometries of \mathbb{R}^2) with self-intersections. Here the word elastica refers to a critical point of the functional F on closed curves.

Proposition 4.8. *Up to isometries of \mathbb{R}^2 the ‘‘Figure Eight’’ (see Figure 1) is the unique minimizer of the functional F between all planar closed curves with at least one self-intersection. One of the two drops of \mathcal{F} is the unique minimizer for Problem 4.3.*

Proof. From the previous lemma we know that the infimum of F between the closed regular curves $\varphi : \mathbb{S}^1 \rightarrow \mathbb{R}^2$ of class H^2 in which there exists at least two points $s_1 \neq s_2 \in \mathbb{S}^1$ such that $\gamma(s_1) = \gamma(s_2)$ is a minimum, hence the minimizer exists and has to be globally an elastica. The unique closed elastica with at least one self-intersection is the ‘‘Figure Eight’’ \mathcal{F} [11, Theorem 0.1 (a)].

Again from the previous lemma we know that the energy of a minimizer among drops is half the energy of a minimizer between the closed curve with at least one self-intersection. As the ‘‘Figure Eight’’ is symmetric, we conclude that a minimizer for Problem 4.3 is one of the two drops of \mathcal{F} . \square

It remains to compute the energy of the “Figure Eight”. Langer and Singer already observed in [10] that the Euler-Lagrange equation of the elasticae can be integrated using Jacobi-Elliptic functions. In [5] the authors found a dynamical system that the components of a planar elastica parametrized by arc-length satisfy. From this dynamical system description one is able to find an explicit parametrization of the “Figure Eight” depending only on well defined parameters. Thanks to this representation we were able to compute in [3, Prop.6.4] the energy of \mathcal{F} .

Lemma 4.9 (see [3]). *Consider the optimal rescaling \mathcal{F} of the “Figure Eight”, then*

$$F(\mathcal{F}) \approx 21.2075.$$

Let us note here that the words “optimal rescaling” would not be necessary in the statement once one defines the “Figure Eight” as the unique (up to multiple coverings and isometries of \mathbb{R}^2) closed planar critical point of $F = F_1$ with self-intersections.

4.4 Minimizers are Theta-networks

We are ready to establish the main result of the paper.

Theorem 4.10. *There exists a minimizer of Problem 2.2.*

Proof. In Proposition 4.8 we have shown that the minimum of problem 4.3 is attained by one of the two drops of the “Figure Eight” \mathcal{F} . As a consequence, the energy of any “degenerate” Theta-network Γ is greater or equal than the energy of \mathcal{F} , that is $\overline{F}(\Gamma) \geq \overline{F}(\mathcal{F}) \approx 21.2075$. By (2.5) the energy of the optimal rescaling of the standard double bubble is $F(\mathcal{B}_{\overline{r}}) \approx 18,4059$. We have exhibit a Theta-network with strictly less energy than every “degenerate” Theta-network. This shows that each minimizer for \overline{F} (whose existence is established in Corollary 3.6) is necessarily a Theta-network. Since \overline{F} is the relaxation of F the first part of the statement follows. \square

With an argument based on Theorem A.1 we can show that minimizers are injective.

Proposition 4.11. *Every minimizer of Problem 2.2 is an injective Theta-network.*

Proof. For simplicity we divide the proof into two steps.

- *Step 1: At most one curve has self-intersections*

Suppose by contradiction that at least two curves, let us say γ^1 and γ^2 , of a minimizer Γ have self-intersections. Then for $i \in \{1, 2\}$ we can decompose γ^i as the union of two curves \mathcal{D}^i and $(\gamma^i \setminus \mathcal{D}^i)$, with \mathcal{D}^i a drop. By Proposition 4.8 and Lemma 4.9 we have that

$$F(\Gamma) \geq F(\gamma^1) + F(\gamma^2) \geq F(\mathcal{D}^1) + F(\mathcal{D}^2) \geq F(\mathcal{F}) > F(\mathcal{B}_{\overline{r}}),$$

hence such a Γ is not a minimizer, a contradiction.

- *Step 2: Each curve is injective*

Suppose that the curve γ^1 has self-intersections. As before γ^1 can be written as the union of two curves \mathcal{D} and $(\gamma^1 \setminus \mathcal{D})$, with \mathcal{D} a drop and clearly $F(\gamma^1) \geq F(\mathcal{D})$. Thanks to Corollary 4.8 we know that the energy of \mathcal{D} is greater or equal than the energy of one drop of the “Figure Eight” \mathcal{F} . Moreover combining Corollary A.3 with Lemma 2.4 we get $F(\gamma^2 \cup \gamma^3) \geq \frac{8\pi}{3}$. Hence

$$F(\Gamma) \geq F(\mathcal{D}) + F(\gamma^2 \cup \gamma^3) \geq \frac{1}{2}F(\mathcal{F}) + \frac{8\pi}{3} \approx 18.9813 > F(\mathcal{B}_{\overline{r}}),$$

a contradiction. \square

Now that we know that each minimizer is a Theta-network it is interesting to understand which boundary conditions a minimizer (or more generally a critical point) in the class of Theta-networks satisfies. The following result is established in [3, Prop.4.1]. See also [1].

Proposition 4.12 (see [3]). *Let $\Gamma = \{\gamma^1, \gamma^2, \gamma^3\}$ be a Theta-network that is a critical point for F . Then each curve $\gamma^i : [0, 1] \rightarrow \mathbb{R}^2$ of Γ is C^∞ and satisfies (4.1) on $(0, 1)$. Moreover, at each junction the following conditions are satisfied*

$$\sum_{i=1}^3 k^i(x) = 0 \text{ and } \sum_{i=1}^3 (2\partial_s k^i \nu^i + (k^i)^2 \partial_s \gamma^i)(x) = 0 \text{ at } x = 0, 1. \quad (4.4)$$

Here k^i is the scalar curvature of γ^i and ν^i is the normal to γ^i , i.e. the counter-clockwise rotation of $\frac{\pi}{2}$ of the tangent $\partial_s \gamma^i$.

A direct consequence of (4.4) is that the standard double bubble of radius r is not a critical point of F , being the second condition in (4.4) not satisfied. Indeed, consider the double bubble given by the curves $\gamma^1, \gamma^2, \gamma^3$ as in Figure 3 with γ^1 oriented counter-clockwise, γ^2 oriented from the right to the left and γ^3 oriented clockwise. Being the curvature constant it is clear that $\partial_s k^i \equiv 0$ for $i = 1, 2, 3$. On the other hand $k^2 \equiv 0$ whereas $k^3(x) = -k^1(x) \equiv -r^{-1}$ for all $x \in [0, 1]$. Since $\partial_s \gamma^1(0) = (\frac{1}{2}, \frac{1}{2}\sqrt{3})$ and $\partial_s \gamma^2(0) = (\frac{1}{2}, -\frac{1}{2}\sqrt{3})$ it follows

$$\sum_{i=1}^3 (2\partial_s k^i \nu^i + (k^i)^2 \partial_s \gamma^i)(0) = r^{-2}(1, 0) \neq (0, 0).$$

Among the qualitative properties that a minimizer could have, we expect global embeddedness, i.e. that there are no intersections (except at the junction points) among the curves of a minimal network. It seems also plausible that one of the three curves of the minimizer is a straight line and that the minimizer is symmetric, as shown in Figure 7.

It would also be interesting to understand what happens if one consider the same minimization problem in \mathbb{R}^n , instead of \mathbb{R}^2 .

Figure 7: Left: The standard double bubble. Right: A possible minimizer. This configuration has been (numerically) obtained by R. Nürnberg, letting evolve the double bubble by the L^2 -gradient flow of the energy F (see also [1]).

5 Generalized Theta-networks

Some of the results just presented can be generalized to a certain family of 3-networks of class H^2 whose curves meet in junctions with fixed angles, that we call generalized Theta-networks. This has already been observed in [3].

Definition 5.1. Let $\alpha_1, \alpha_2, \alpha_3 \in (0, 2\pi)$ be such that $\sum_{i=1}^3 \alpha_i = 2\pi$. Then a *generalized* $(\alpha_1, \alpha_2, \alpha_3)$ *Theta-network* is a 3-network $\Gamma = \{\gamma^1, \gamma^2, \gamma^3\}$ such that the three curves are of class H^2 , regular and meet at each triple junctions with fixed angles α_1 between γ^1 and γ^2 , α_2 between γ^2 and γ^3 and, as a consequence, α_3 between γ^3 and γ^1 .

Without loss in generality we may assume that $0 < \alpha_1 \leq \alpha_2 \leq \alpha_3 < 2\pi$. Also in this setting the scaling arguments apply and hence we can consider simply the functional F .

Upper bound on the energy. A competitor is the generalized $(\alpha_1, \alpha_2, \alpha_3)$ Theta-network given by two arc of circles joined by a segment. The energy of the optimal rescaling is computed in [3] and is given by

$$F(B_{opt}) = 4\sqrt{\alpha_1 + \frac{\alpha_2 \sin \alpha_2}{\sin \alpha_1}} \sqrt{\alpha_1 + \alpha_2 \frac{\sin \alpha_1}{\sin \alpha_2} + \sin \alpha_1}.$$

Extension. In analogy to Definition 3.2 we define \bar{F} the extension of F to 3-networks Γ of class H^2 .

Definition 5.2. A “degenerate” *generalized* $(\alpha_1, \alpha_2, \alpha_3)$ *Theta-network* is a network composed by two regular curves of class H^2 , forming angles in pairs of α_i and $\pi - \alpha_i$ degrees, for some $i \in \{1, 2, 3\}$, and by a curve of length zero.

Then the functional \bar{F} is defined as follows: $\bar{F}(\Gamma) = F(\Gamma)$ if Γ is a generalized $(\alpha_1, \alpha_2, \alpha_3)$ Theta-network,

$$\bar{F}(\Gamma) = \sum_{i=1}^2 \int_{\gamma^i} (k^i)^2 + 1 \, ds^i$$

if $\Gamma = \{\gamma^1, \gamma^2\}$ is a “degenerate” generalized $(\alpha_1, \alpha_2, \alpha_3)$ Theta-network and equal to $+\infty$ otherwise.

Existence of minimizers of the relaxed energy. To show the compactness \bar{F} it was crucial the application of Theorem A.1. The same arguments work also in this setting. In particular with a variant of Corollary A.3 (due to the different angles) one gets an estimate similar to (3.1) from which one still can argue that only the length of one of the curves might go to zero at the limit.

Once the existence of minimizers for \bar{F} is established, it remains to see when one can show that the minimizers are not “degenerate” Theta-networks. Reasoning as above, in [3, pages 112-113] it is shown that this is the case when $\alpha_1 \leq \alpha_2 \leq \frac{3}{4}\pi$. For general angles $(\alpha_1, \alpha_2, \alpha_3)$ this is still an open problem.

A An estimate on the curvature

Consider a continuous, piecewise $W^{2,1}$, regular closed curve $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ possibly with angles (points in which the unit tangent vector does not change in a continuous way) and possibly with self-intersections. Our aim is to find a uniform estimate for the integral of the modulus of the curvature along the curve γ based on the classical Gauss–Bonnet theorem.

Figure 8: A curve with external angles $\tilde{\theta}_i$ and $\tilde{\theta}_j$.

Let $0 = x_0 < x_1 < x_2 \dots < x_N = 1$ be a partition of $[0, 1]$ such that γ is of class $W^{2,1}$ on each interval $[x_{i-1}, x_i]$, $i \in \{1, \dots, N\}$. We call $\gamma(x_i)$ vertices. In the following, for each i , θ_i denotes the (positive) angle between the unit tangent vectors $\tau(x_i^-) = \partial_s \gamma(x_i^-)$ and $\tau(x_i^+) = \partial_s \gamma(x_i^+)$. More precisely, at each vertex we fix $\theta_i \in [0, \pi]$, $i \in \{1, \dots, N\}$, such that

$$\cos(\theta_i) = \frac{\langle \gamma'(x_i^-), \gamma'(x_i^+) \rangle}{|\gamma'(x_i^-)| |\gamma'(x_i^+)|}, \quad (\text{A.1})$$

with the usual convention that $x_N^+ := x_0^+$. Notice that the angles θ_i do not depend on the parametrization and the orientation.

Theorem A.1. *Consider a continuous, piecewise $W^{2,1}$, regular closed curve $\gamma : [0, 1] \rightarrow \mathbb{R}^2$, possibly with angles θ_i , $i \in \{1, \dots, N\}$, at the vertices $\gamma(x_i)$. Then*

$$\int_{\gamma} |k| ds \geq 2\pi - \sum_{i=1}^N \theta_i. \quad (\text{A.2})$$

Proof. We first suppose that the closed curve $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ is piecewise C^∞ , regular, possibly with angles θ_i , $i \in \{1, \dots, N\}$, at the vertices $\gamma(x_i)$ and possibly with finitely many self-intersection but not at the vertices $\gamma(x_i)$. Then the claim in the general case follows by approximation, combining the fact that C^k is dense in $W^{2,1}$ and the density of the considered class of curve into rectifiable curves. This approximation argument is given in detail in Appendix B.

We prove the statement by induction on the number of self-intersections of γ .

Suppose first that the curve γ has no self-intersections and hence γ is a simple closed curve. The claim then follows from the classical Gauss–Bonnet Theorem [6, pag. 269]. Let us shortly discuss the ideas. Without loss of generality we can assume that the curve is positively oriented. For all $\theta_i \in [0, \pi]$, $i \in \{1, \dots, N\}$, we define the external angles $\tilde{\theta}_i$ as follows: $\tilde{\theta}_i = \theta_i$ if $\gamma'(x_i^+)$ is obtained by a counterclockwise rotation of $\gamma'(x_i^-)$ and $\tilde{\theta}_i = -\theta_i$ otherwise (and we refer to [6, pages 265–267] for the more delicate definition of $\tilde{\theta}_i$ in the case $\theta_i = \pi$). Then, $\tilde{\theta}_i \in [-\pi, \pi]$. The classical

Gauss–Bonnet Theorem [6, pag. 269] yields

$$\int_{\gamma} k \, ds = 2\pi - \sum_{i=1}^N \tilde{\theta}_i.$$

Hence

$$\int_{\gamma} |k| \, ds \geq \int_{\gamma} k \, ds = 2\pi - \sum_{i=1}^N \tilde{\theta}_i \geq 2\pi - \sum_{i=1}^N \theta_i.$$

Let us assume now that Formula (A.2) holds true for every curve with at most n self–intersections and consider a curve γ with $n + 1$ self–intersections. Then we can decompose γ as union of two curves, $\gamma^1, \gamma^2 : [0, 1] \rightarrow \mathbb{R}^2$, each with at most n self–intersections, so that: γ^1 has M angles θ_i ($M \leq N$) and an angle β (with $0 \leq \beta \leq \pi$) at $\gamma^1(0) = \gamma^1(1)$ and the curve $\gamma^2 : [0, 1] \rightarrow \mathbb{R}^2$ has $N - M$ angles and an angle β (with $0 \leq \beta \leq \pi$) at $\gamma^2(0) = \gamma^2(1)$. Then by the induction assumption we get

$$\begin{aligned} \int_{\gamma} |k| \, ds &= \int_{\gamma^1} |k| \, ds + \int_{\gamma^2} |k| \, ds \geq 2\pi - \sum_{i=1}^M \theta_i - \beta + 2\pi - \sum_{i=M+1}^N \theta_i - \beta \\ &= 4\pi - \sum_{i=1}^N \theta_i - 2\beta \geq 2\pi - \sum_{i=1}^N \theta_i. \end{aligned}$$

□

Corollary A.2. Consider a regular curve $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ of class $W^{2,1}$, such that $\gamma(0) = \gamma(1)$. Then

$$\int_{\gamma} |k| \, ds \geq \pi.$$

Proof. Since γ has only an angle with arbitrary amplitude $\theta \in [0, \pi]$ the claim follows directly from (A.2). □

Corollary A.3. Consider a regular closed curve $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ piecewise of class $W^{2,1}$, with two equal angles $\theta_i = \frac{\pi}{3}$. Then

$$\int_{\gamma^1 \cup \gamma^2} |k| \, ds \geq \frac{4\pi}{3}.$$

Proof. Also in this case the statement is a direct consequence of (A.2). □

B An approximation lemma

In this section we give the details of the approximation argument used in the proof of Theorem A.1. The concept of *transversality* of curves turns out to be crucial in our argument.

Definition B.1. Consider two curves $\gamma, \tilde{\gamma} : [0, 1] \rightarrow \mathbb{R}^2$ of class C^k (with $k = 1, 2, \dots$). We say that

1. A curve γ is *self-transversal* if at each self–intersection $\gamma(x) = \gamma(\tilde{x})$ with $x \neq \tilde{x}$ the derivatives $\gamma'(x)$ and $\gamma'(\tilde{x})$ are linearly independent.

2. Two curves $\gamma, \tilde{\gamma}$ are *transversal* if at each intersection $\gamma(x) = \tilde{\gamma}(\tilde{x})$ the derivatives $\gamma'(x)$ and $\tilde{\gamma}'(\tilde{x})$ are linearly independent.
3. Consider a piecewise C^k curve $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ and let $0 = x_0 < x_1 < x_2 \dots < x_N = 1$ be a partition of $[0, 1]$ such that $\gamma|_{[x_{i-1}, x_i]}$ is of class C^k for $i \in \{1, \dots, N\}$. Then γ is *self-transversal* if $\gamma|_{[x_{i-1}, x_i]}$ is self-transversal for every $i \in \{1, \dots, N\}$ and the curves $\gamma|_{[x_{i-1}, x_i]}$ and $\gamma|_{[x_{j-1}, x_j]}$ are transversal for $i \neq j, i, j \in \{1, \dots, N\}$.

Remark B.2. Notice that if a curve γ is *regular*, then every point in the image of the curve has a finite number of preimages. Moreover, a compactness argument yields that every *self-transversal* curve has a finite number of self-intersections. Similarly, if two curves $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ and $\tilde{\gamma} : [0, 1] \rightarrow \mathbb{R}^2$ are regular and transversal, then they have a finite number of intersections and the number of couples (x, \tilde{x}) with $x, \tilde{x} \in [0, 1]$ and $\gamma(x) = \tilde{\gamma}(\tilde{x})$ is finite.

In the next result we describe how to approximate a piecewise C^k regular closed curve, $\gamma : [0, 1] \rightarrow \mathbb{R}^2$, possibly with angles θ_i ($i \in \{1, \dots, N\}$) at the vertices $\gamma(x_i)$, with closed curves $\tilde{\gamma} : [0, 1] \rightarrow \mathbb{R}^2$ which are piecewise C^∞ , regular, and with finitely many self-intersections (but non at the vertices).

Lemma B.3 (Approximation). *Let $k = 1, 2, \dots$, consider a continuous closed curve $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ and let $0 = x_0 < x_1 < x_2 \dots < x_N = 1$ be a partition of $[0, 1]$ such that γ is of class C^k and regular on each interval $[x_{i-1}, x_i]$. Then for every $\varepsilon > 0$ there exists $\tilde{\gamma} : [0, 1] \rightarrow \mathbb{R}^2$ an approximating continuous closed curve which is of class C^∞ and regular on each interval $[x_{i-1}, x_i]$ and such that*

1. $\|\gamma - \tilde{\gamma}\|_{C^k[x_{i-1}, x_i]} \leq \varepsilon$;
2. $\tilde{\gamma}$ is self-transversal;
3. $\tilde{\gamma}$ has no self-intersections at the vertices $\tilde{\gamma}(x_i)$, $i \in \{1, \dots, N\}$.

Proof. Step 1: Construction of an approximating curve without self-intersections at the vertices
 Since there are only finitely many vertices it is sufficient to consider each one separately. Suppose that γ has self-intersections at the vertex $\gamma(x_1)$. Since γ is regular, $\partial_x \gamma(x_1^-) \neq 0$. Then at least one component of $\partial_x \gamma(x_1^-)$ is different from zero and, by continuity, there exists $\eta_1 > 0$ such that this component of $\partial_x \gamma(x)$ is different from zero for all $x \in [x_1 - \eta_1, x_1]$ and also satisfying $x_1 - \eta_1 \geq \frac{1}{2}x_1$. Similarly $\partial_x \gamma(x_1^+) \neq 0$, hence we can find $\eta_2 > 0$ such that $x_1 + \eta_2 \leq \frac{1}{2}(x_1 + x_2)$ and such that $\gamma(x) \neq \gamma(x_1)$ for all $x \in [x_1, x_1 + \eta_2]$.

Let η be equal to the smallest number between η_1 and η_2 and take $\psi : [0, 1] \rightarrow [0, 1]$ of class C^∞ with support contained in $(x_1 - \eta, x_1 + \eta)$ and equal to one in $(x_1 - \frac{1}{2}\eta, x_1 + \frac{1}{2}\eta)$ and otherwise taking values between 0 and 1. Consider now the curve $\hat{\gamma} = \gamma + v\psi$ where the vector v in \mathbb{R}^2 should be chosen such that

1. $|v| \|\psi\|_{C^k(x_1 - \eta, x_1 + \eta)} \leq \frac{1}{4}\varepsilon$;
2. $\hat{\gamma}(x_0) \notin \text{Im}(\gamma)$;
3. for every $x \in [x_1 - \eta, x_1]$ (respectively in $[x_1, x_1 + \eta]$) a component of $\partial_x \hat{\gamma}$ (the same of $\partial_x \gamma$) is different from zero.

Condition 1. and 3. are satisfied by choosing v small enough and as $\mathcal{H}^2(\text{Im}(\gamma)) = 0$ all conditions can be achieved. Then

- condition 1. implies that $\|\gamma - \hat{\gamma}\|_{C^k([x_{i-1}, x_i])} \leq \frac{1}{4}\varepsilon$ for $i = 1, 2$;
- condition 2. implies that $\hat{\gamma}(x_1) \neq \hat{\gamma}(x)$ with $x \in ([0, 1] \setminus [x_1 - \eta, x_1 + \eta])$;
- condition 3. implies that $\hat{\gamma}(x_1) \neq \hat{\gamma}(x)$ with $x \in [x_1 - \eta, x_1 + \eta]$.

Hence by construction $\hat{\gamma}$ has a vertex in x_1 but no self-intersections at this vertex.

If $\hat{\gamma}$ has self-intersections at the vertices $\hat{\gamma}(x_i)$, $i \in \{2, \dots, N\}$, one has to repeat the approximation procedure described above at each vertex. For simplicity we still call the new approximating curve so obtained $\hat{\gamma}$.

Step 2: Construction of a self-transversal approximating curve

For every $i \in \{1, \dots, N\}$ let $\hat{\gamma}^i$ be the restriction of the curve $\hat{\gamma}$ to the interval $[x_{i-1}, x_i]$. For every $\varepsilon > 0$ and for every $i \in \{1, \dots, N\}$ there exists a curve $\tilde{\gamma}^i : [x_{i-1}, x_i] \rightarrow \mathbb{R}^2$ of class C^∞ , self-transversal, such that for all $j \in \{1, \dots, N\}$ with $j < i$ the curves $\tilde{\gamma}^i$ and $\tilde{\gamma}^j$ are transversal and $\|\hat{\gamma}^i - \tilde{\gamma}^i\|_{C^k([x_{i-1}, x_i])} \leq \varepsilon/2$. The key lemmas are the following: the family of regular curves of class C^k and self-transversal is open and dense in $(C^k, \|\cdot\|_{C^k})$ (see Theorem 1.1 of Chapter 1, Theorem 2.12 of Chapter 2 and Exercise 2 of Section 2 in Chapter 3 in [9]) and the family of all regular curves of class C^k and transversal to a given curve is open and dense in $(C^k, \|\cdot\|_{C^k})$ (see Theorem 2.1(b) in Chapter 3 in [9]).

The desired approximating curve $\tilde{\gamma}$ is given by the union of all the $\tilde{\gamma}^i$ and therefore is continuous, piecewise C^∞ curve and regular. \square
